Classification of Compact Surfaces

Theorem (The Classification of Surfaces)

Every closed, connected surface is homeomorphic to exactly one of:

- the **sphere** S^2 ,
- a **connected sum of n tori** $T^2 \# \cdots \# T^2$ ($n \geq 1$), or
- a **connected sum of m projective planes** $\mathbb{RP}^2 \# \cdots \# \mathbb{RP}^2$ ($m \geq 1$).

The proof follows the same strategy as the classification of **closed prime surfaces**.

Key Definitions and Facts

Definition

A surface S is **prime** $\iff S$ contains no essential separating simple closed curve.

Key Definitions and Facts

Lemma

Every closed connected surface S admits a polygonal representation.

The proof proceeds by considering a surface's triangulation (S, K) and its spanning tree T , and inductively removing vertices from T to construct a polygonal representation of S .

Step 1: Reducing Adjacent Identified Edges

Lemma

The sphere S^2 , the torus $T^2 = S^1 \times S^1$ and the real projective plane $\mathbb{RP}^2$ are the only prime surfaces.

Proof: Let P be a polygonal representation of a prime surface S . Suppose two **adjacent edges** of P are identified like in the picture:

Figure 2.11. Redundant edges in a polygonal representation of S .

We may identify them to obtain a polygon with **fewer edges**, so set P to be the polygonal representation of S with the fewest possible number of edges.

Step 1: Reducing Adjacent Identified Edges

Special case: Suppose P has two adjacent edges pointing in the same direction, with *no other edges*.

- Then $S \cong \mathbb{RP}^2$.

Figure 1.4. The projective plane obtained from a bigon via identifications.

Special case: Suppose P has two adjacent edges pointing in the same direction, with other edges present.

- The dotted arc separating these edges must cut a disc off the other side (otherwise S is not prime).
- Hence $S \cong \mathbb{RP}^2$.

Figure 2.12. A polygonal representation of S containing a projective plane.

Assumption henceforth: No two adjacent edges of P are identified.

Step 2: Curves Arising from Arcs in P

Let c be a simple closed curve in S realized by an arc in P connecting a pair of identified edges.

We consider two cases based on whether c is **separating** or **nonseparating**. Suppose then that c is **separating**. Then c cuts S into two components S_1 and S_2 .

Figure: Regions S_1 , S_2 , induced by a separating curve c .

Step 2a: The Separating Case

Since S is **prime**, one component, say S_2 , must be a **disc**.

- This disc S_2 meets remnants of edges of P .
- Therefore, there is a polygonal representation of S with **fewer edges**.

Figure: Regions S_1 , S_2 , induced by a separating curve c .

We replace P with this smaller polygon and continue.

Step 2b: The Nonseparating Case

Suppose c is **nonseparating**.

- Let a be a simple closed curve intersecting c **exactly once**.
- Let $C(c \cup a)$ be a **collar neighborhood** of $c \cup a$ in S .

Figure 2.13. The curve c and arc a .

One can show that $C(c \cup a)$ is homeomorphic to one of:

- 1 a **torus minus a disc**,
- 2 a **Klein bottle minus a disc**, or
- 3 a **Möbius band minus a disc**.

Figure: $\mathbb{T}^2$ minus a disc, $\mathbb{K}^2$ minus a disc

In each case, the boundary curve(s) of $C(c \cup a)$ must **bound discs** in S .

Step 2b: Conclusion of the Nonseparating Case

Recall the three cases for $C(c \cup a)$:

- ① **Torus minus a disc:** The boundary bounds a disc in S , so $S \cong T^2$.
- ② **Klein bottle minus a disc:** This would require $S \cong K$, but the Klein bottle is **not prime** (since $K \cong \mathbb{RP}^2 \# \mathbb{RP}^2$).
- ③ **Möbius band minus a disc:** The boundary bounds a disc in S , so $S \cong \mathbb{RP}^2$.

Note: The sphere is a prime surface, by Jordan Curve Theorem.

Conclusion: The only closed prime surfaces are S^2 , T^2 , and $\mathbb{RP}^2$.

From Prime Surfaces to the Full Classification

Another way to look at it is... every compact surface decomposes as a **connected sum of prime surfaces**:

$$S \cong P_1 \# P_2 \# \cdots \# P_n$$

where each P_i is prime.

Since the only prime closed surfaces are S^2 , T^2 , and $\mathbb{RP}^2$:

- The decomposition of a surface into prime surfaces, as if $S = S_1 \# S_2$, then S_1 and S_2 admit polygonal representations whose polygons have fewer vertices than the one of S .

From Prime Surfaces to the Full Classification

Lemma

$$T^2 \# \mathbb{RP}^2 = \mathbb{RP}^2 \# \mathbb{RP}^2 \# \mathbb{RP}^2$$
